Introduction

TETRA-SL LL is brown-feathered layer for cage or alternative systems. Pedigree lines of TETRA-SL LL are selected for their viability, efficient and long-term egg production as well as superior internal and external egg quality. Genetic selection of pure lines is an ongoing task for Bábolna TETRA geneticists to maintain and improve the quality and performance of grandparent, parent and commercial stocks.

This extended manual is a guideline and information source for maximizing your profits and satisfaction with your stocks; although special requests due to climatic or lighting conditions may require assistance from your nearest Bábolna TETRA specialist. We believe that by following this Management Guide and keeping accurate records, the results of your flock will gradually improve year by year.

BÁBOLNA TETRA

TETRA – Selected for Quality

In recent decades, the consumer market has undergone some significant changes, resulting in increased expectations towards production stocks. The key to this adaptation is a properly structured and efficient selection programme supported by a systematically developed consulting network, which lies behind the increasing popularity of Bábolna TETRA parent stock and their progenies.

Continuous investment over the last years, such as a new pedigree farm and high-capacity layer breeder hatchery, has enabled the creation of a larger base for selection and more efficient and safer hatching for their valued customers. Close contact with the market is essential for the development of their products and to fulfill long-term needs, hence TETRA will continue to actively participate in product fairs and organize partner meetings in the future.

Nowadays, Bábolna TETRA is determined to improve the competitiveness of their poultry, which has a long tradition and increasing share in the global market. Despite the diversity of the current market, TETRA focuses on the selection

of the most important traits (persistency, egg quality, viability) and is determined to stabilize economic performance of their stocks for all technological environment. Current test capabilities ensure that individual and group progeny tests are carried out until 90-100 weeks of age.

The success of the company's R&D programme has been greatly due to its cooperation with partner institutions over many decades. Thanks to this, results of *in vivo* (CT) examination of the hens and their eggs, welfare indicators (state of plumage, pecking, etc.) and behavioral observations have been used in the selection index of pure lines for years. Intensive selection work continues to preserve a calm temperament and minimize beak trimming.

TETRA selection

Performance Data of TETRA-SL LL Commercial Layer

Table 1.

Livability	
0-17 weeks of age	97-98%
18-90 weeks of age	93-95%
Feed consumption	
0-17 weeks of age	5.7-6.0 kg
18-90 weeks of age (average)	108-112 g/day
Bodyweight	
At 17 weeks of age	1.41 kg
At 90 weeks of age	1.9-2.0 kg
Maturity	
Age at 50% production	140-144 day
Age at 90% production	161-163 day
Egg production per hen housed	
Until 72 weeks of age	318-322
Until 80 weeks of age	360-365
Until 90 weeks of age	408-412
Egg mass	
Until 72 weeks of age	20.2 kg
Until 80 weeks of age	23.0 kg
Until 90 weeks of age	26.3 kg
Egg weight (weekly average)	
In 32 weeks of age	61.9 g
In 52 weeks of age	65.0 g
In 80 weeks of age	67.2 g
In 90 weeks of age	67.5 g
Average egg weight	64.1 g
Shell strength	>35 N
Shell colour	brown

General Recommendations and Biosecurity of Poultry Farms

General rules

- Isolation of the house is vitally important to reduce the possibility of introducing a disease organism into a clean house environment.
- People traffic constitutes the largest threat to isolation and the introduction of disease-causing agents. Ideally, shower facilities and farm clothing are to be made available for all employees and necessary visitors.

Keep out cars and other vehicles from the farm area, only allowing minimal traffic. Always use sanitizing liquid to carry out proper disinfection.

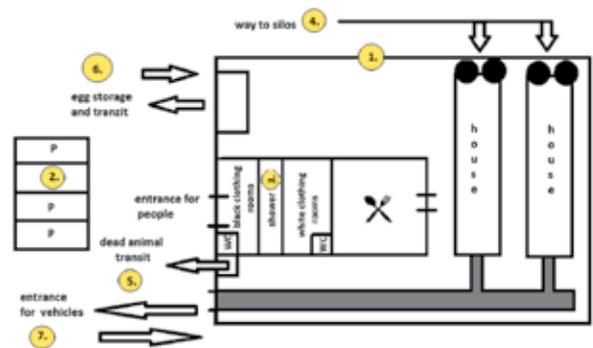

- If this is not possible, visits should be limited to only those persons that are necessary and they should be required to wear clean coveralls, new plastic or cleaned rubber boots and hair covering.
- Disinfectant footbaths should be present at the entranceway to each house and should be replenished with fresh disinfectant daily.
- Doors should be kept locked at all times to prevent unwanted, improperly attired visitors from entering. NO TRESPASSING signs should be prominently displayed on the doors and BIOSECURITY ZONE signs should be displayed at the farm entrance to warn visitors that they are entering a biosecure area.
- Remembering that people spread many diseases from farm to farm will help to encourage less people traffic to and from farms.

The importance of biosecurity

Pathogens can reach your flock in hundreds of different ways, such as feed, wild birds, rodents, insects, day-old chicks, visitors, trucks, equipment and other flocks. These pathogens (bacteria, viruses, fungi, etc.) can cause poor performance as well as outbreaks of diseases. This is why TETRA takes it very seriously indeed. It is far easier to prevent these problems from occurring, than cure or eradicate your flock.

Plan and build

Before building a farm, one has to consider some important facts. It is best to start building it with a good deal of planning and great attention to detail, otherwise it is more difficult to change it after it has been constructed.

1. Fence around the farm
2. Parking facilities for visitors
3. Black and white clothing room
4. Way to silos
5. Dead animal transfer
6. Egg storage
7. Entrance for the vehicles

Location

Put your farm as far as possible from any other farms to reduce the risk of contamination. Avoid high traffic motorways, where poultry transfer is very common. Take care to prevent ingress of air-borne hazards.

Single-age flock

Avoid horizontal contamination by housing single-age flocks. One farm should contain same age and same breeding level chickens. Separate growing and laying farms are welcomed. Hatcheries closely located to feed mixing plants and slaughter houses increase the transmission of infection.

Visitors

Follow the black (dirty) and white (clean) principle. Erect a fence around your farm with a closed entrance (sign with UNAUTHORIZED ENTRY PROHIBITED). Everything outside the farm is "black", and inside is "white". Minimize the number of visitors, entering only when it is required. Set up parking facilities outside of the fence. Visitors are not allowed to enter by car.

Around the poultry houses

The surroundings of the houses are to be kept free of vegetation as wild birds prefer this, clean and place a 0.5-1 m strip of stone close to the wall of the poultry houses to deter rodents.

Construct the wall with smooth materials, which are stainless, so it can be easily washed with liquid, containing detergent or disinfectant.

Personal hygiene

Before entering, use boot and hand disinfectant. Provide a "black and white" clothing room inside the biosecurity building, located at the fence line. Visitors have to change their clothes and remove their personal belongings. Before entering the poultry house, change your boots and use them only inside of the house. Wear different boots on the farm, and inside of each house. Keep your environment clean: sweep and clean biosecurity rooms, poultry house entrance and surrounding roads.

Traffic inside the farm

The best choice is, when no vehicles enter the farm.

- **Feed:** Put silos near to the fence so the truck can fill them from outside.
- **Dead birds:** Collect them minimum once a day and place them in a collecting box along the line of the fence. This has to be closed and preferably cooled while, the frequency of removal depends on temperature as well.

- **Egg storage:** Place the egg storage building far from other areas.

If you cannot avoid vehicles entering the farm (day-old chicks, litter, manure transfer, slaughter house vehicles), disinfect them thoroughly, especially the wheels with a high-pressure washer. Please consult your veterinarian in choosing the right disinfectant. If it is necessary for the driver to get out of the truck, he/she must wear disposable clothes and boots. Entry to the poultry house for the driver is prohibited.

Book for visitors

Create a book for visitors. Each person has to write his name, the purpose of visit, date, and declare when he/she was visiting poultry facility, hatchery, slaughter house, feed mill in the last two weeks. If you have to visit more flocks than one, follow this rule: at first, visit the younger flocks, and only then the older ones: the higher ones first, then the lower breeding level. Everything must be recorded in the visitors' book.

Cleaning and disinfection

The most effective way to reduce the negative impact of disease-causing pathogens on the growth and subsequent performance of a laying flock is to avoid exposure to these organisms. A sound sanitation program and effective isolation plans are instrumental in achieving this goal. Cleaning and disinfection is of prime importance to prevent reinfection of the new flock, coming to the farm. After depopulation, all the hiding birds and bodies must be removed. An insecticide program is most effective when applied immediately in a still warm house environment.

The flexible part of the equipment has to be disassembled, while manure and litter must be eliminated. Transfer the litter far from the farm to a fermentation plant, but do not spill onto the road while doing that. The residue of the feed must be removed from the silos, bins and feeders. Dry cleaning should be done as soon as possible after the old flock is removed.

Soak the inside and equipment of the house for hours, use tensides and sufficient liquid.

High pressure cleaners perform cleaning well, using effective detergent in cold or hot water. Do not forget feeders, drinkers, fans, air in- and outlets. Rinsing with water is the next step, after that allow the equipment and house to dry.

Always use a broad spectrum sanitizing agent for proper disinfection of the poultry houses between flocks.

Use a multi-level disinfection programme in order to reduce the number of germs in the house. Take care with walls, floors, fan blades, lights, slats, nests, feeders and drinkers, outside and inside. Do not forget closed areas, like sanitation and store rooms. An effective disinfection requires clean surfaces without any remaining dirty or organic material. The dosage and the application time of the disinfectant must be properly calculated. Use disinfectants with antiviral, antibacterial and antifungal effect. Sporocides kill very resistant parasite spores as well. Change active ingredients frequently and monitor the effect by microbiological tests. Take care that some disinfectants do not work well under low temperature. Disinfectants can harm human health, so follow instructions thoroughly and use personal protection.

Cleaning and disinfection involve not only chicken houses, but all the farm area as well, included biosecurity building, feed store, litter store, egg store etc. Do not forget vehicles, tools, clothes and boots.

Water hygiene

Water and watering systems require regular checks and maintenance. The water quality has to be checked every 6 months for microbiological and chemical compounds. Chlorinate the water when necessary. When the house is empty, use effective detergents and disinfectants to remove biofilm and carbonate deposits from the pipeline.

When there are any birds in the house, water lines must be flushed frequently in hot weather conditions, before and after vaccination or medication.

Feed hygiene

Feed quality is of prime importance. Buy feed from certified and controlled suppliers. When you mix feed by yourself, use high-quality ingredients and premixes. Nutritional content, energy and protein balance, macro- and microelements, enzymes are necessary for good development and performance. Microbial contamination (bacteria, fungi) and toxins (mainly mycotoxins) should be avoided. Heat treatment reduces bacterial germs, use toxin binding substances when needed. For Salmonella control, use appropriate supplements. Pelleting the feed means heat treatment and better homogeneity after handling. Layer breeders prefer crumbled feed. Hygienically storing and transporting the feed is also important. The surrounding of silos, feed bins must be kept clean, spilled feed should be removed immediately, so as not to attract wild birds. Silos must be emptied and cleaned regularly, so two silos are preferred to each of the houses.

Wild bird and rodent control

Wild bird and rodent control is the first line of defence against transmission of dangerous diseases. It is important to prevent viral, bacteriological and parasitic infections and for this purpose, bird-nets are to be used. Doors and walls must be intact, so as to prevent entry of wild animals. Avoid spilling of feed, remove dead birds and broken eggs. Implement a rodent control program.

Housing

Before the arrival of the new flock

Raise the house temperature to 34-35°C at least 24 hours prior to chick arrival to ensure the equipment is also warm. The desired relative humidity should be greater than 60%. This humidity level should be maintained for at least three weeks.

- Set light clocks to 23 hours per day with the light intensity as high as possible (20-30 Lux). If any shadows are being cast onto any drinkers/nipples, the use of droplights is suggested to eliminate them.
- Trigger nipples to ensure that they are in working order and set at the proper height. Nipples should be at the chick's eye level and bell drinkers should be on the floor. Supplemental drinkers should be used during floor brooding and removed slowly once the chicks are established and are clearly using the main drinking system.

Brooding period

For TETRA-SL LL commercial stock, the use of spot brooding is recommended. Heat is provided by conventional canopy brooders while rearing space can be divided into half by a curtain to save on space and energy costs.

Table 2: Temperature requirements for TETRA-SL LL pullets

Age in days	Brooding temperature (°C) on chicks's level
Day old	35
1-4	34-35
5-7	32
8-14	30
15-21	27
22-28	24
29-35	22
35-119	20

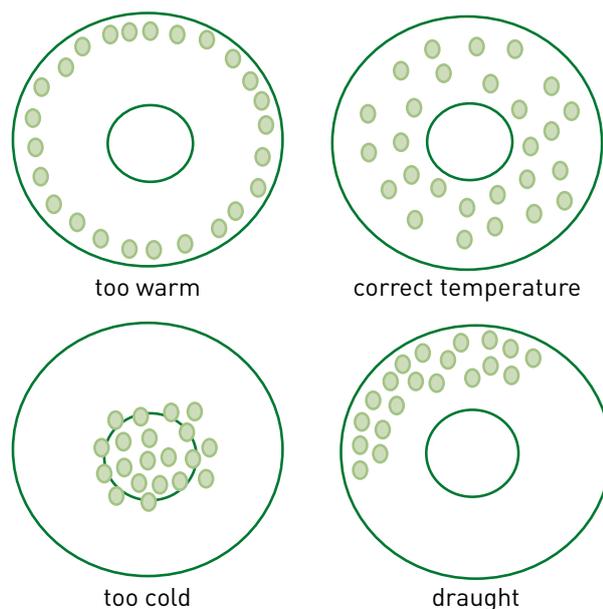

Checklist

- The behaviour of the chickens is the best indicator of the temperature, especially during night. By following some simple rules, we can ensure the conformity of the chicks during this fragile period.

- If the birds are calm and quiet and are spread equally in the house, it means they feel comfortable.
- Always measure the temperature at the bird's level.
- Besides the temperature, it is essential to maintain proper humidity as well, especially if brooding in cages. Relative humidity has to be kept between 60-70% by evaporating water (floor brooding) or watering the walks (cage brooding) if necessary.

Figure 1: Indication of chick's well-being during brooding

Growth Management

TARGETS:

- Flock uniformity and bodyweight are the predictors of future laying performance of the birds
- Ensure that targets stated in this manual are reached in the main points of their development (change in feed type)
- Keep records of mortality, feed intake, feed conversion ratio, water consumption and weekly bodyweight

Stocking density

Environmental factors, such as type of housing, ventilation and temperature, have a greater effect upon stocking rate than genetic. The following recommendations (Table 2.) are given as a guide for floor and cage rearing. These rates should be reduced by 2-3% for each 1°C rise in temperature.

Feeding space

Standard should be regarded as the minimum requirements for a satisfactory performance.

Drinking space

Water is essential by itself. It can also influence nutrient intakes by controlling feed intake. Restriction on water intake will cause a voluntary reduction in feed intake.

To ensure that all birds find water when initially housed, there should be a minimum light intensity of 20 Lux at bird level. This is especially important at one day-old and where a change of drinking system occurs when moving birds into the laying house.

Table 3: Standards for TETRA-SL LL pullets

Age in weeks		0-6	7-17	over 17
Density (bird/m ²)	Floor	20-24	10-12	7
	Cage	50-80	25-40	13-18 (minimum 490 cm ²) – non-EU 10-13 (minimum 750 cm ²) – EU
Drinking space	Birds/nipple	10-12	8	4-6
	Birds/drinker (ø 46 cm)	100-130		
Feeding space	Through or circular feeder (space/bird)	4 cm + extra feeding surface in first week	7 cm	10 cm

Checklist: Cover the cage floor with paper and place feed on it. Check the availability of feed and water.

Beak trimming

Beak trimming need not be carried out routinely when stock is kept in a controlled environment. If experience from previous flocks suggests that it is necessary, it will be worthwhile first checking all other aspects of management before embarking on a programme of beak trimming. The provision of more feeders and drinkers, more space per bird, correct nutritional components or improved ventilation may be the correct action to take.

- Infrared treatment is the most recommended method for beak trimming, which can be done soon after hatching, when chicks are dried up.

- Beak trimming can also be done at about 7-8 days of age. In order to reduce stress, it should be delayed for flocks where the brooding conditions have not been suitable or adequate.
- In open-sided housing, routine beak trimming is recommended, as both bright light intensities and high temperatures may promote undesirable behavior. Care must always be taken that all birds are correctly and uniformly beak trimmed.
- Each bird should mature with a rounded, but slightly shortened, beak and be able to conduct normal feeding activity

Vaccination programmes

Always consult your local vet as rules are constantly changing according to each country's own regulations.

Table 4: Example of a vaccination program for TETRA-SL LL commercial stock

Disease	Suggested time of application	Occurrence
Marek's disease (MD)	First day at the hatchery	**
Newcastle disease (ND)	The number of vaccination is depending on disease pressure in that area (suggestion: Day 1 and 12, Week 6 and 15 and before transfer)	**
Infectious bronchitis (IB)	The number of vaccination is depending on disease pressure in that area (suggestion: Day 1 and 12, Week 6, 11 and 15 and before transfer)	**
Gumboro disease (IBD)	Two vaccinations (Day 18 and 28) recommended	**
Avian encephalomyelitis (AE)	The number of vaccination is depending on disease pressure in that area (suggestion: Week 9)	*
Avian pneumovirus (APV)	Vaccination around Week 13 and before transfer	**
Coccidiosis	Vaccination is recommended on the first day (on the farm)	**
Mycoplasma synoviae (MS)	Vaccination around Week 8	**
Salmonella	Two live and one inactivated vaccine is recommended (Suggestion: Day 5 and Week 7; before transfer)	*
Fowl pox (FP)	Vaccination around Week 8	*
E. coli	Vaccination around Week 8	**
EDS	Vaccination before transfer	*

** : Worldwide; * : Locally

Nutrition

The genetic potential of TETRA-SL LL layers with high performance may only be exploited when their biological needs are met. The feeding of complete feed is necessary, with specialized nutrient content which is adapted to the animals' needs in respect of each production phase. This is a topic that the feed industry nowadays specializes in; a mix of state-of-the-art technology and up to date physiological knowledge in order to perform new tasks.

The basics

Energy and nutrients

Due to the high productivity of intensive layers, the demand for nutrients is relatively high and varied. Scientific studies classified up to almost 40 (macro and micro) nutrients that are to be supplied in appropriate concentrations and ratios.

Energy demand is considered to be the most important factor. The recorded feed digestion (burning) provides energy for the body, a part of which (metabolizable energy or ME) can be utilized for metabolic processes such as subsistence, weight gain and production.

Proteins and amino acids

Protein is the highest proportion of components in the body, feathers and eggs, therefore it is essential for growth and production. The "crude protein" content has become less valued in scientific circles, although it still has great significance in practice. Simple laboratory tests (N x 6.25) and rapid tests are available in order to monitor the protein content of the feed, which is necessary to control the reliability of the manufacturing plant.

In fact, protein added in the feed is broken down into amino acids, from which the body compiles its own proteins, but their genetically-encoded amino acid composition and sequence is different. About 20 different amino acids are required, some of which poultry cannot synthesize, known as 'essential' amino acids, as well as those 'non-essential' amino acids only found in a very limited amount in the feed. Methionine and lysine supplements are now required in almost all poultry feed, with threonine and valin usually being indicated on the values that set limits on excessive protein reduction. Birds require cystine for their plumage whereas, in its absence, it is produced by sulphur-containing methionine]

Fats, oils, fatty acids

Components of fats/oils are fatty acids. Their ratio affects their melting point (solid "fats" and liquid "oils"). All power provider compounds, like fatty acids, especially linoleic acid, are essential for the growth and development of skin and feathers, the development of the reproductive tract and are also considered to be essential in terms of eggshell formation. The linoleic acid content of maize, sunflower and soybean oil is favourably high.

Minerals

Calcium (Ca) and phosphorus (P), quantitatively are the most important components of eggshell and bone and are also present in other tissues of the body. Grain-based feeds are poor in calcium, so ground limestone (calcium carbonate, 38% Ca) supplementation is necessary. However, plants contain a higher proportion of phosphorus but, because of phytin connections, the bioavailability of P rate is only 10-40%. Previously, a large-scale mineral phosphate supplement was needed although, today, because of the wide-range use of phytase enzyme, P-utilization has significantly improved.

Sodium (Na⁺), potassium (K⁺) and chloride (Cl⁻) ions play an important role in blood and osmotic pressure, maintaining the pH of cells while also activating enzymes. Sodium supplements with common salt (NaCl) usually satisfy the chlorine demand. In the case of heat stress, in the form of sodium carbonate supplementation is recommended. The potassium (K⁺) content in plants is already known to be high.

Vitamins, microelements

Vitamins are micronutrients that are essential for maintaining health, fertility and performance. Each vitamin has a separate function which is not able to be performed by other vitamins. Vitamins – with few exceptions – cannot be synthesized, so they must be

introduced by feed. For the supply of vital functions, a few milligrams or micrograms of certain vitamins is sufficient, but this must be provided on a regular basis. In today's intensive technology, satisfactory results can only be achieved by a purpose-built vitamin supply.

Trace elements are components of enzymes, each of which play a crucial role in certain metabolic processes. Regular poultry feeds contain a compound of 13 different vitamins and 7 trace elements; incorporation of Vitamin C is recommended in the case of increased stress. Certain poultry feed contains the same vitamins and trace elements but their amount and utilization is not suitable for layers selected for their high performance – partial absence of either micro-component has a noticeable negative impact on health and production.

Other supplements and additives

- Regular mixing of antioxidants protects vitamins and unsaturated fatty acids.
- In recent decades, the exogenous enzymes have caused major changes and NSP-degrading (non-starch polysaccharides) enzymes have allowed a higher grade, risk-free mixing of cereals, while the phytase enzyme has strongly improved phosphorus utilization of plant components, as well as favourably affects the digestibility of other nutrients.
- Specific additives in layer feeds are carotenoids, which make the egg yolk more attractive for consumers in some countries.

Feeding during Growing Period

By following the recommendations in our feeding program, described in TETRA Management Guide, pullets achieve their weight in accordance with their age. This is an essential condition for normal sexual maturity in addition to starting and maintaining a high level of production during the laying period.

During the various phases of development, differently composed feed is recommended for chicks and pullets to accommodate the nutritional requirements of the birds themselves. The actual weight of the flock must be considered before moving on to the next level. If pullets have not reached the desired weight by the end of a growing period, any feed changes need to be delayed.

Grain size

For chicks, pullets and hens, coarsely grained ("structured") diets are the most appropriate, although excessively coarse feed leads to selective eating whereas too fine feed structure causes reduced feed intake and, as a result, uneven nutrition in both cases.

In starter feeds (especially in the first phase) crumbs are the most appropriate, which in terms of the microbiological status, means increased security for the feeding of young chicks.

Pre-starter, Starter (0-3 weeks; 4-8 weeks)

Essentially Starter rations aim to produce a good skeleton, good organ development and help to promote an active immune system. This is achieved by feeding the Starter *ad libitum*

during the first week, with the correct balance and absolute levels of essential amino acids for growth, development of the immune system, feathering and skin condition.

Grower (9-16 weeks)

Whilst the Grower diet will be the lowest density ration that the bird receives, with higher fibre content, while it is important that all nutrients are correctly included. Fibres positively influence the development of the digestive tract and consequently, the appetite. It is very important that young layers are able to take all nutrients that they need, at the start of their production. We recommend to use 5-6% crude fibre in the grower diet for TETRA-SL LL pullets. Cereals and their by-products as well as DDGS can be used as a source of crude fibre.

Feed restriction is not recommended during this period as it may be difficult to achieve the correct bodyweight at first egg. As feeding portions are being increased, it is essential to monitor bodyweight weekly during this period.

Pre-layer (17-19 weeks)

Pre-layer feed is a transition from Grower to Layer I, with not only a significantly increased calcium content, but also a higher level of each nutrient. Pre-layer feed should compensate lower feed intake, that often occurs at the start of production. During this period, the layers undergo significant physiological changes. The medulla of a layer's tubular bones are developed which provides the calcification of the shell calcium content in the egg production period.

An adequate amount of calcium is important to be added at this time, for proper bone strength and egg shell quality during production. Increased levels of energy and amino acids are also desirable since these promote the development of the ovarian tissue. The daily weight gain of 10-15 grams increases 3-15 days before the onset of egg production. In order to begin egg production, a target of 1500-1550 grams bodyweight should be achieved and *ad libitum* feeding of properly prepared Pre-layer feed is necessary.

Clean water should always be available and its quality need to be checked regularly.

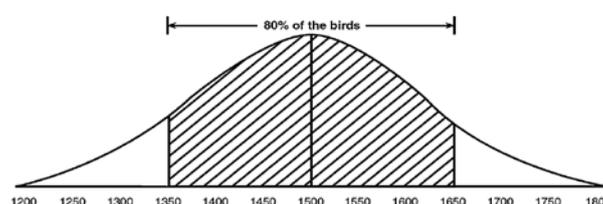

Bodyweight control during rearing

Uniformity and regular weighing is of utmost important. During the growing period and until peak production is reached, regular weighing must be carried out. The measurement is always done at the same hour of the same day of the week. Regular weighing should have been started in the first few weeks, and it need to be continued weekly, during the growing period. Changes in bodyweight and homogeneity of the stock provide information about normal development of TETRA birds. The growth of a flock is normal and the birds can be considered equal if their CV% is below 10%.

$$\text{CV\%} = \left(\frac{\text{standard deviation}}{\text{average bodyweight}} \right) \times 100$$

TETRA hybrid pullets are not prone to obesity, so if the data obtained during the weighing does not differ significantly from the technological value ($\pm 5\%$) and is recorded as homogeneous, *ad libitum* feeding can be used throughout the rearing period.

If the pullets, nevertheless, do not reach the required weight value, feed consumption by frequent running of the feeders might be used and feed with higher nutritional value should be implemented. The average bodyweight of Tetra-SL LL pullets at the time of transfer should be around 1350-1400 g, at 16-17 weeks of age.

Uniform flock of TETRA-SL LL pullets

Table 5: Nutritional recommendation for TETRA-SL LL pullets

Feed type		Pre-starter	Starter	Grower	Pre-layer
Nutrient		0-3 weeks	4-8 weeks	9-16 weeks	17-19 weeks
Met. energy	MJ/kg	12.35	12.00	11.50	11.70
Met. energy	kcal/kg	2950	2870	2750	2800

*Always check average bodyweight of the flock before switching to the next level of feed type. Unless the bodyweight is lower than stated in TETRA-SL LL Management Guide, do not move on from one diet type to another. Measure the bodyweight frequently, until the birds reach the target weights.

Production Period

Management into lay (15 weeks to peak production)

The target at the beginning of this period is 5-10% average production at the age of transfer.

Minimize variation in bodyweight and sexual maturity of the birds. Prepare the flock for the production period with extra calcium-phosphorus and introduce larger feed particles. Slow transfer from Pre-layer feed to Layer 1, when first eggs appear (>5%)

Management during production

TETRA-SLLL birds are suitable for alternative keeping systems during the production period. In hot climates, it is advisable to provide shelter (house, trees, sheds) and extra drinking and living space for the birds. Controlled environmental houses are more suitable for all-year production programmes.

Bodyweight should be monitored every week until 30 weeks of age, then on a monthly basis.

Overweight hens lay fewer eggs during their production cycle, therefore daily feed consumption should be adjusted to the bodyweight standard.

Control of uniformity

- Hens are usually transferred to the poultry house around 16-18 weeks of age. Bodyweight should be closely monitored until the onset of production.
- Flock uniformity must be the main target. The more uniform the flock is, the quicker will the increase in production be. It is advised to split the daily amount of feed, giving the first round in the morning just before switching on the lights and, subsequently, distributing the rest of the feed after the peak laying hours.
- The level of feed intake in the production period is mainly affected by bodyweight, temperature, feathering, energy level and texture of the feed and production intensity.

- Laying hens primarily alter their daily feed intake to accommodate changes in their energy requirements. Therefore, factors which alter the bird's demand for energy, such as ambient temperature, automatically affect the bird's feed intake. If there has been no modification of the ration formulation, changes in daily intake will result in changes in all nutrient including amino acids, vitamins, minerals, anti-coccidials, that will correspondingly affect bird's performance.
- Hens do not completely adjust their feed intake due to extremes of temperature or higher dietary energy concentration. In fact, high temperatures or high energy concentrations can overly reduce energy intake and egg output suffers as a result.
- Hens with low bodyweight lay fewer eggs, whereas higher bodyweight at the beginning of the production will be an advantage until the peak period.
- Recommendations for cage free systems

The keeping of laying hens in deep litter, aviary and free-range systems requires considerably more expertise than the conventional battery cage system. A detailed guideline for alternative systems, based on field experiences and commercial flock database from different part of the world, is available on our website (www.babolnatetra.com).

Feeding during production period

First eggs appear at 19-20 weeks of age and more can be expected from Week 21 (141-147 days). The daily feed intake increases from 90 to 100 grams between Weeks 20 and 24. During this period, an intensive high-energy and nutritious diet needs to be fed, with increased calcium supplementation.

Table 7: Weight development and feed consumption of TETRA-SL LL layers

Age in weeks	TETRA-SL LL				
	Bodyweight (g)		Feed consumption		
	Average	Range	Average g/bird/day	Range	Cumulative
20	1 650	1 600 - 1 700	90	87 - 93	0.6
21	1 720	1 670 - 1 760	93	90 - 96	1.3

60	1 975	1 935 - 2 015	111	108 - 114	31.0
70	1 985	1 945 - 2 025	111	108 - 114	38.8
80	1 995	1 955 - 2 035	110	107 - 113	46.6
90	2 000	1 960 - 2 040	110	107 - 113	54.3

** : Feed amount must be adjusted to the production intensity and uniformity. Check bodyweight weekly around peak production, increase daily feed amount for hens as production intensity rises.

Layer diets

Layer I.

At the start of egg production daily feed intake rises relatively slowly. At the same time the formation of the egg, the increasing egg weight and bodyweight gain further enhance the nutritional requirements of the layers. It is important to understand that the quality of nutrition has a crucial impact on when they reach peak production and how they perform during persistency. Feeding is ad libitum and any factors which would reduce the feed uptake should be minimized. We recommend feeding Layer I with high nutrient concentrations, as long as production is expected to be over 90% (42-46 weeks of age).

Layer II-IV.

With increasing age, both the production of eggs and the nutritional needs of the birds decrease. In order to optimize costs, lower concentrations of energy and less expensive feeds are allowed. To prevent fattening, energy or fat/oil supplementation, should also be reduced. A proper ratio of nutrients should also be closely monitored during this period. The specific recommendations for feed ingredients are shown in Tables 7 and 8. Layer II should be fed as long as the production is over 80% (65-67 weeks of age), Layer III would be recommended over 70% production (66-80 weeks), and at the end Layer IV could be used.

Table 8: Nutritional recommendation for TETRA-SL LL layers with average daily feed consumption (110 g/day)

Feed type	Layer I	Layer II	Layer III	Layer IV	Layer I	Layer II	Layer III	Layer IV

Values in Table 8 gives the opportunity to make recommendations in the event of different feed consumptions than average (lower or higher), on the basis of the daily nutritional needs. In the case of higher feed intake (115 g / day), a moderate-intensity diet is needed, while with a lower than average (105 g / day) feed consumption, the diet should be more concentrated.

Table 9: Nutritional recommendation for TETRA-SL LL layers with different daily feed consumptions

Vitamin and Micro-Nutrient Supplementation

According to the general introduction stated earlier in this manual, vitamins, trace elements and, if necessary, other additives are always to be present in the diet, in micro amounts. For Starter, higher doses are recommended, which may be reduced in Grower, whereas a higher dose is used in layer diets. The micronutrient supplementation is uniform for all age groups.

Table 10: Vitamins and micro-nutrient recommendation for TETRA-SL LL pullets and layers

Added vitamins		Starters	Grower	Layers
Vitamin A	IU/kg	10 000	10 000	10 000
Vitamin D3	IU/kg	3000	2500	3000
Vitamin E	mg/kg	30	20	25
Vitamin K	mg/kg	3	2	2
Vitamin B1	mg/kg	2	2	2
Vitamin B2	mg/kg	6	4	6
Vitamin B6	mg/kg	4	2	3
Vitamin B12	mcg/kg	20	10	20
Panhotenic acid	mg/kg	12	8	8
Niacin	mg/kg	40	30	30
Biotin	mcg/kg	100	100	100
Folic acid	mg/kg	2	1	1
Choline	mg/kg	400	300	400
Vitamin C (*in case of stress)	mg/kg			50-100*
ADDED TRACE ELEMENTS				
Iron	mg/kg		50	
Manganese	mg/kg		100	
Copper	mg/kg		8	
Zinc	mg/kg		80	
Iodine	mg/kg		1	
Selenium	mg/kg		0.3	

Limestone additions

In accordance with the calcium (Ca) requirements for hens, it must be present in their feed in high proportions. In addition, the quantity and shape of limestone is equally important. A lower content of Ca in the diet causes a higher feed intake, which leads to an uneven supply of nutrients. On the other hand, excess Ca supply has a controversial effect on consumption, causing the remaining nutrient supply to become insufficient.

Table 11: Supply of fine- and coarse limestone (recommended ratio within diet)

Feed type	Fine (<0.5 mm)	Coarse (1.5-3.5 mm)
Layer I (19-45 weeks)	35%	65%
Layer II (46-65 weeks)	30%	70%
Layer III (66-80 weeks)	25%	75%
Layer IV (81-90 weeks)	20%	80%

I Feeding and Egg Quality

Higher bodyweight reached by the end of rearing causes higher egg weight values during production. Among nutrient components, crude protein, methionine and the proportion of linoleic acid within the diet have a positive effect on egg weight.

Shell strength is a complex trait in that many factors are known to affect the quality of the egg shell. These include age, egg weight, the animal's behavior, lighting programmes, feeding,

disease and drugs, ambient temperatures and the feeding technology used.

Calcium content, being the most important mineral, plays a key role in the egg shell formation but other minerals, vitamins and nutrients are also involved. The balance of all the different minerals, as well as the total amount of each component, are equally important for normal egg shell formation.

I Egg Handling

Nests

- The production of clean eggs and the minimization of eggs laid on the floor are influenced greatly by the provision of sufficient, well-sited and maintained nest boxes. Floor eggs should be avoided, because of contaminations, cracking and excess work for collection. Nests should be well-ventilated to discourage broodiness and their litter replenished regularly to prevent breakages and minimize bacterial contamination.

Egg collection

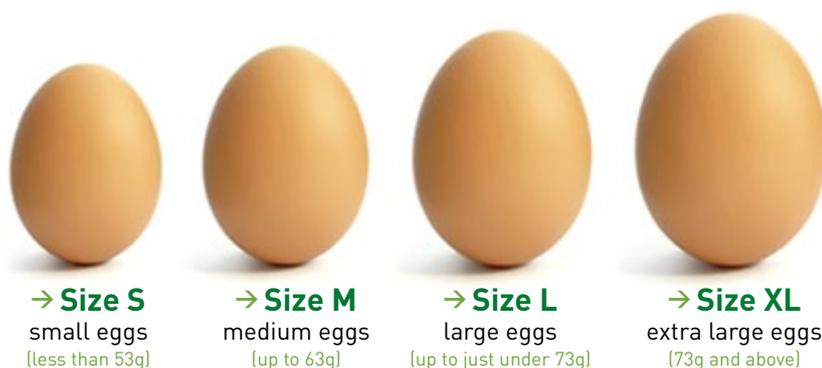

- Flock size and the number of nests determine the number of eggs to be collected.
- Eggs should be collected from nests at least 4 times a day. Most eggs will be laid during the morning hours, so collection times should be adjusted accordingly.
- Floor eggs must be collected and handled separately. Percentage of floor eggs must be registered, so management factors can be changed accordingly.

Lighting Programmes

- A lighting programme is only effective if direct sunlight is blocked from entering the building, otherwise the time of maturity can vary. Due to this reason, flocks moved to lay in autumn will start to produce eggs a few weeks later than stated in this manual.
- The principal function of a lighting programme is to influence the age at which a flock becomes sexually mature.
- Age, and more particularly bodyweight at first egg is the main factor, which determines the package of egg output. Egg numbers during the laying period decreases by 3-4 eggs for each 10-day delay in age at first egg.

Figure 2: Lighting programme for TETRA-SL LL pullets and layers

- Bright light is necessary for the chicks to feed and drink properly. Therefore, light intensity should be monitored, especially in the first 2-3 weeks.

Controlled environment (dark house)

- When birds are reared in a controlled environment, the onset of production is relatively easy to handle.
- After transferring the birds, the hours of lighting must be increased until 16 hours.
- Do **not** decrease the length of lighting during the production period.
- Full benefits will not be obtained if the house is not light-proof, especially when birds are being reared during a time of naturally-increasing day length. In such circumstances, early sexual maturity and small egg size are potential problems.

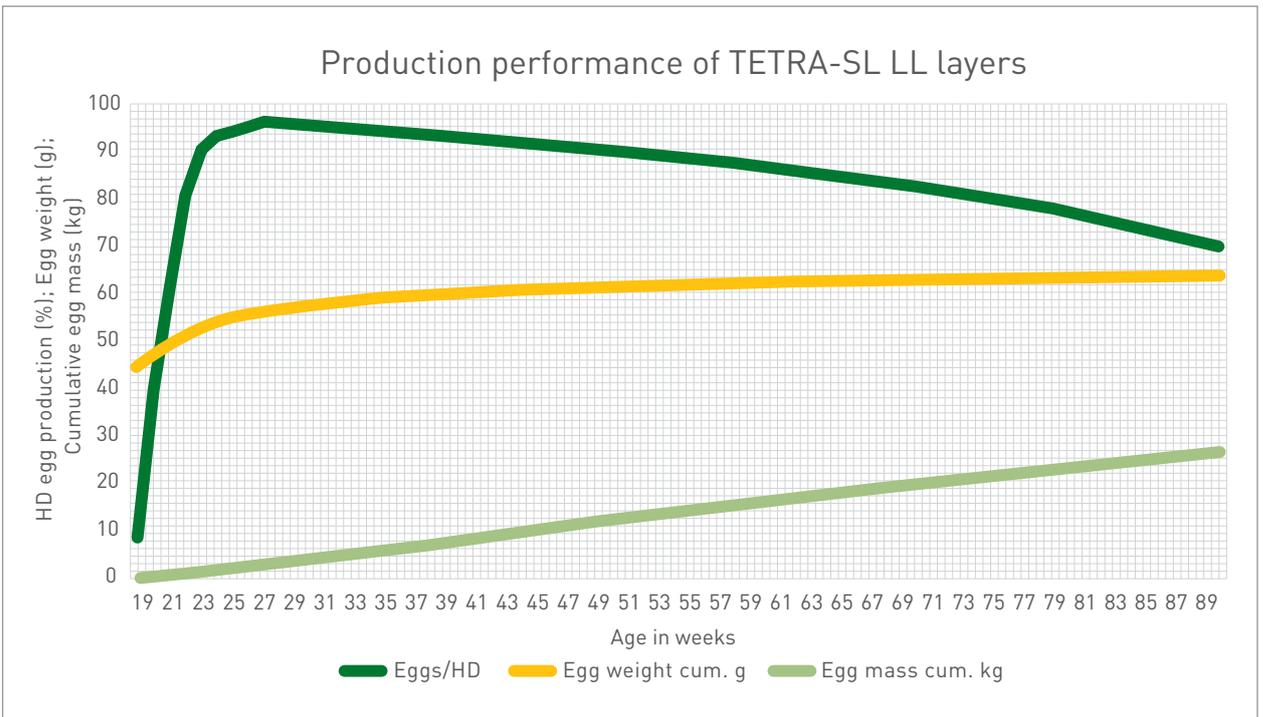

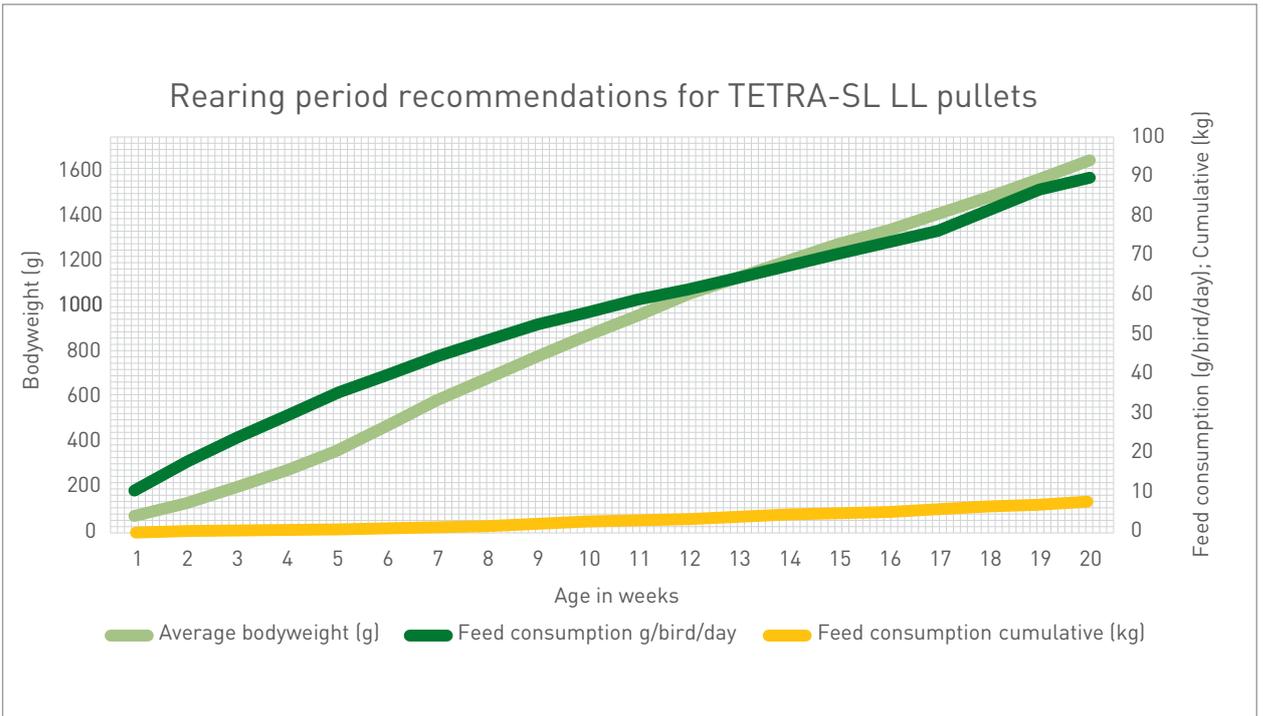

Table 15: Detailed lighting programmes for TETRA-SL LL layers

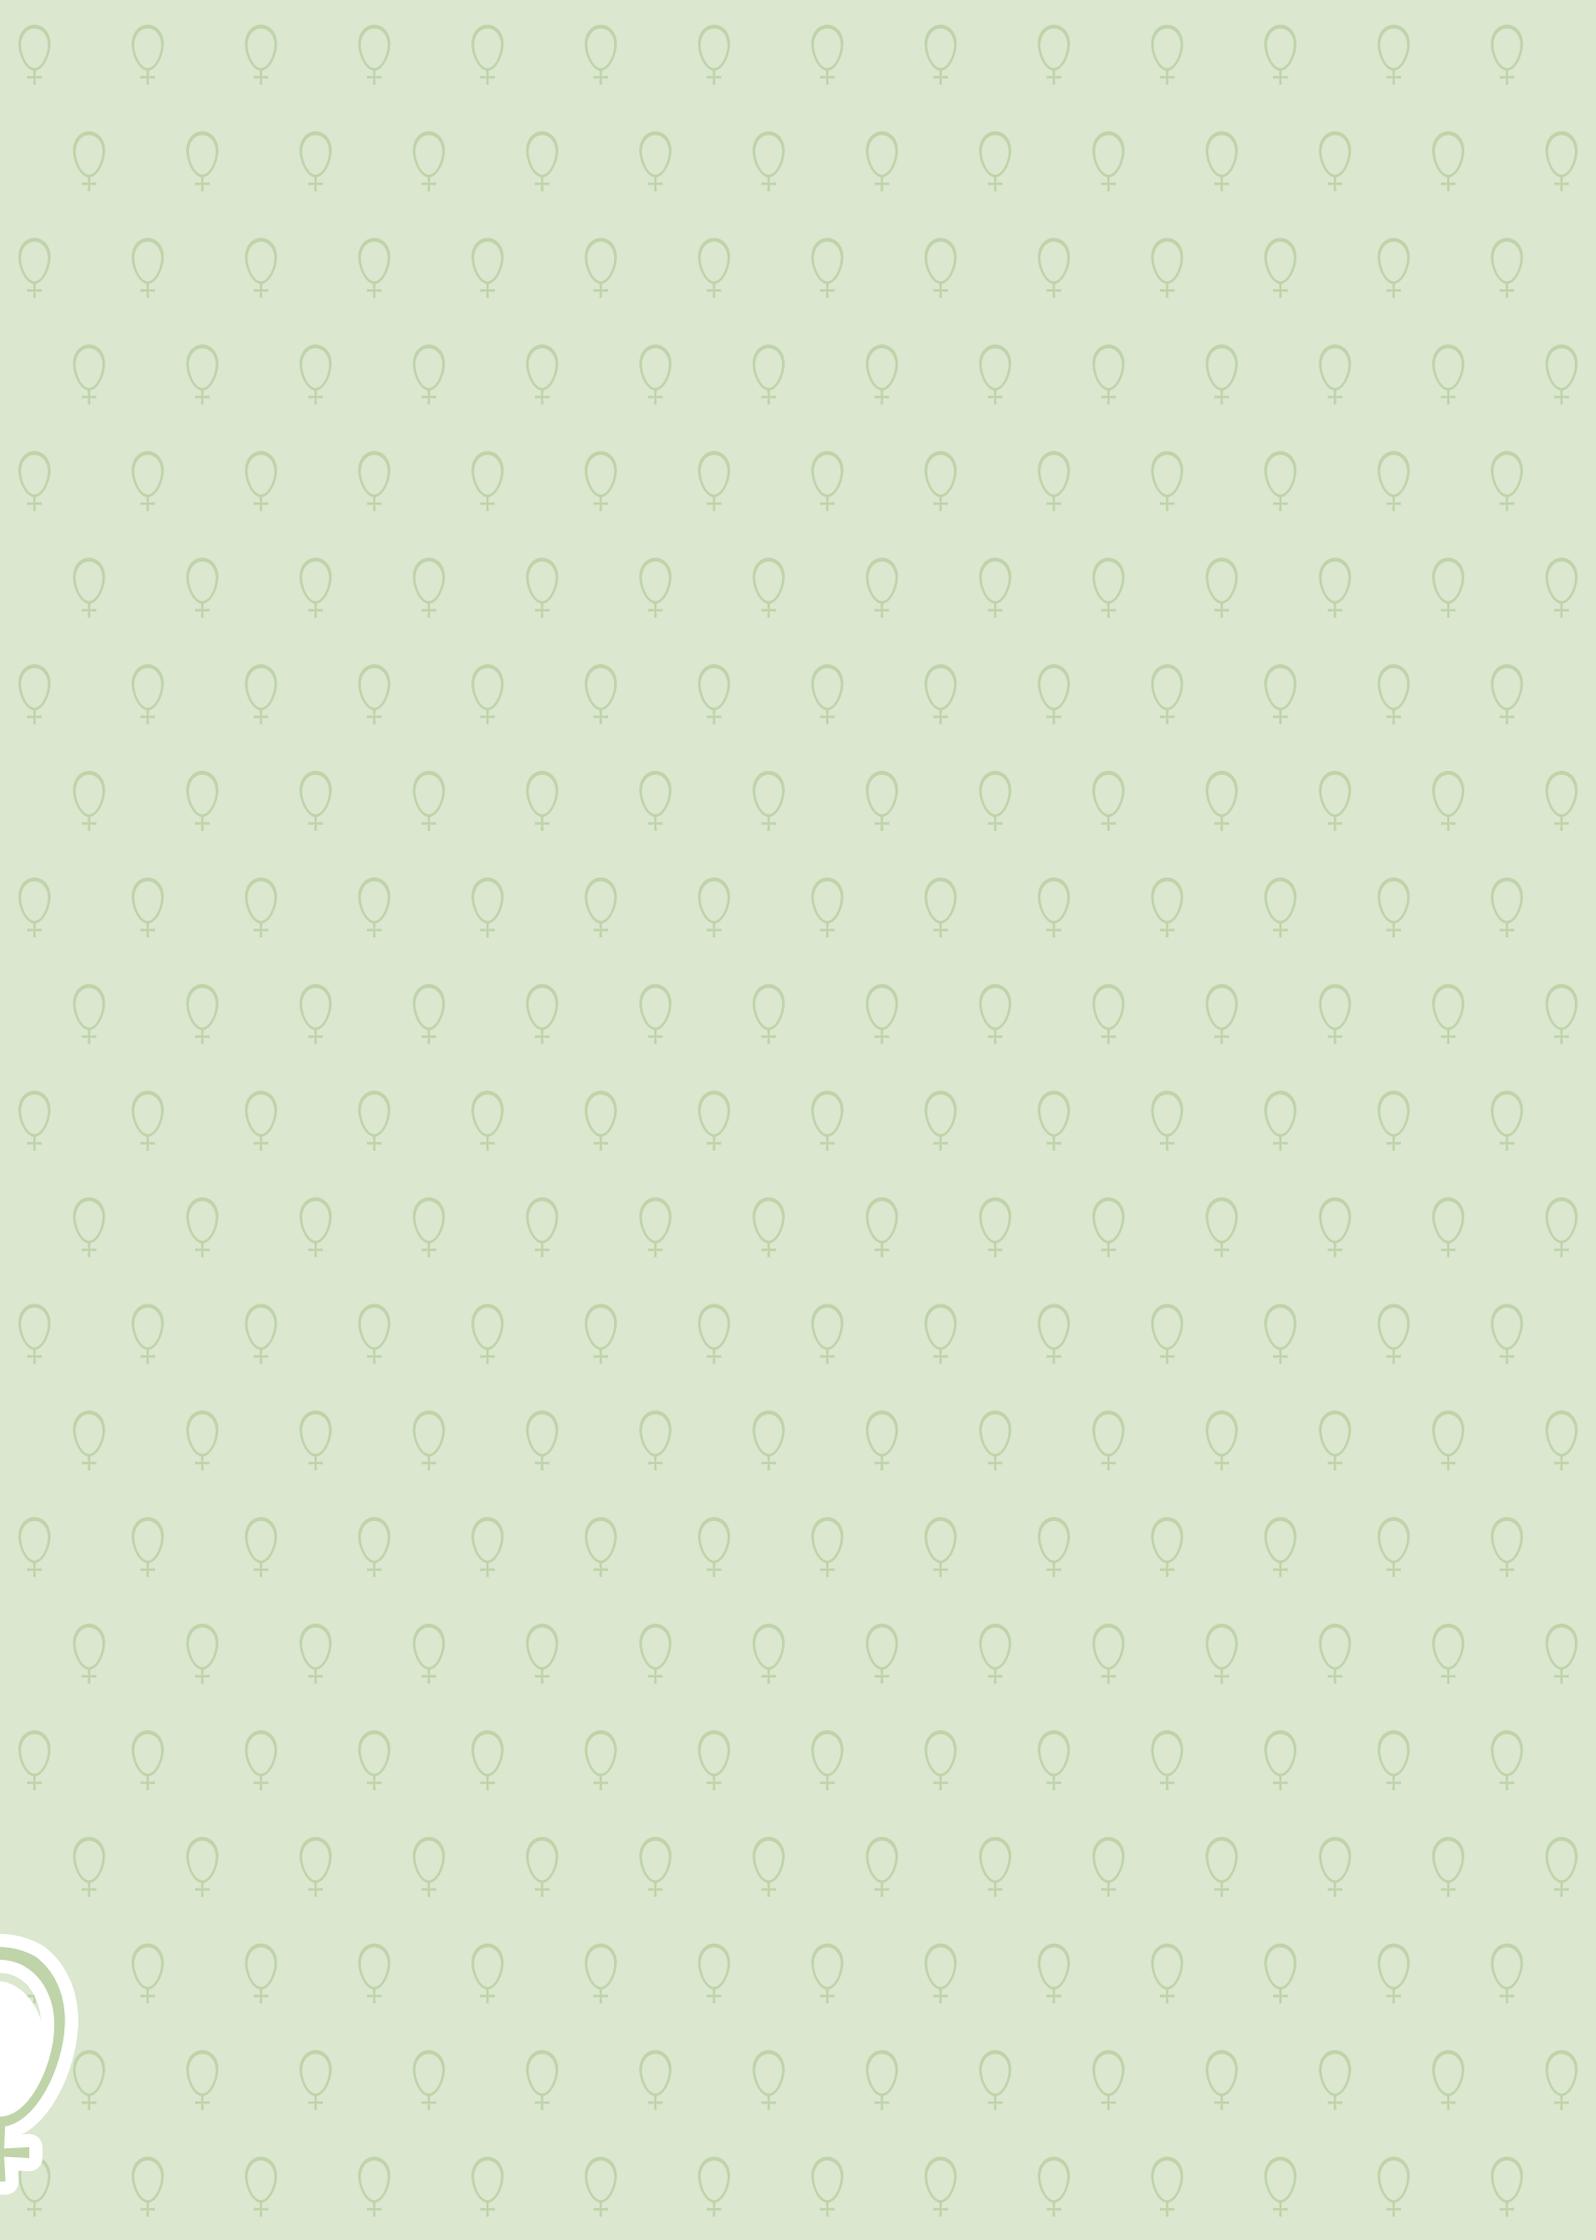

Age in weeks	Hours of light	Light intensity (Lux)
1	22	20-30
2	20	10-20
3	19	10-20
4	18	5-10
5	17	5-10
6	14	5-10
7	11	5-10
8	10	5-10
9	10	5-10
10	10	5-10
11	10	5-10
12	10	5-10
13	10	5-10
14	10	5-10
15	10	5-10
16	10	5-10
17	12	5-10
18	13	5-10
19	13.5	5-10
20	14	10-12
21	14.5	10-12
22	15	10-12
23	15.5	10-12
24	16	10-12
25	16	10-12

Open-house environment

- Light stimulation is not necessary when birds are transferred to an open-sided or free range environment.
- Any adjustment to the lighting programme is dependent on the following:
 - Natural daylight increases
 - Natural daylight decreases
- For example; when the TETRA-SL LL flock starts production in late winter/spring or when the natural day length increases in the Northern Hemisphere, it is advised not to transfer them before natural sexual maturity (21-22 weeks of age).
- Personalized lighting programmes for regional climatic and lighting conditions are available from your **Bábolna TETRA representatives**.
